

# Network Security

Nauman Israr

# Objectives

---

- ▶ Define attacks:
- ▶ Describe defenses
- ▶ Identify techniques
  
- ▶ Acknowledgements
  - ▶ *Slides adopted from Computer Networking: A Top Down Approach* by Jim Kurose, Keith Ross and Justin Weisz's tutorial, CISA review Manual and other Network Security sources

# The Problem of Network Security

---

The Internet allows an attacker to attack from anywhere in the world from their home desk.

They just need to find one vulnerability: a security analyst need to close every vulnerability.

# What is network security?

---

***confidentiality:*** only sender, intended receiver should “understand” message contents

- ▶ sender encrypts message
- ▶ receiver decrypts message

***authentication:*** sender, receiver want to confirm identity of each other

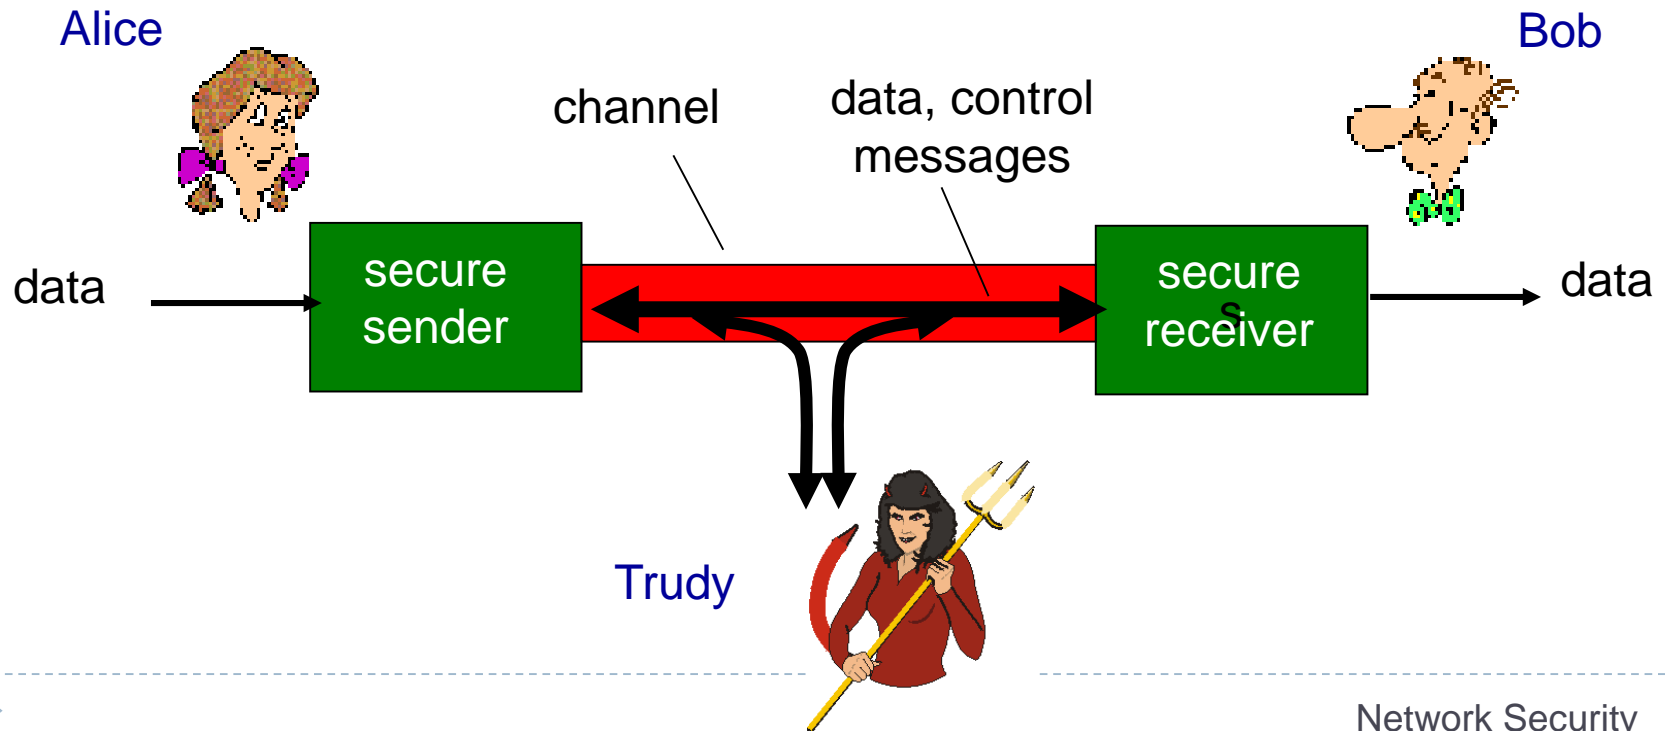

***message integrity:*** sender, receiver want to ensure message not altered (in transit, or afterwards) without detection

***access and availability:*** services must be accessible and available to users

# Friends and enemies: Alice, Bob, Trudy

- ▶ well-known in network security world
- ▶ Bob, Alice want to communicate “securely”
- ▶ Trudy (intruder) may intercept, delete, add messages

# Who might Bob, Alice be?

---

- ▶ ... well, *real-life* Bobs and Alices!
- ▶ Web browser/server for electronic transactions (e.g., on-line purchases)
- ▶ on-line banking client/server
- ▶ DNS servers
- ▶ routers exchanging routing table updates
- ▶ other examples?

# There are bad guys (and girls) out there!

---

Q: What can a “bad guy” do?

A: A lot!

- ▶ *Eavesdrop:*
- ▶ *insert* messages
- ▶ *Impersonation:*
- ▶ *Hijacking:*
- ▶ *denial of service:*

# Passive Attacks

---

**Eavesdropping:** Listen to packets from other parties  
= **Sniffing**

**Traffic Analysis:** Learn about network from observing traffic patterns

**Footprinting:** Test to determine software installed on system =  
**Network Mapping**

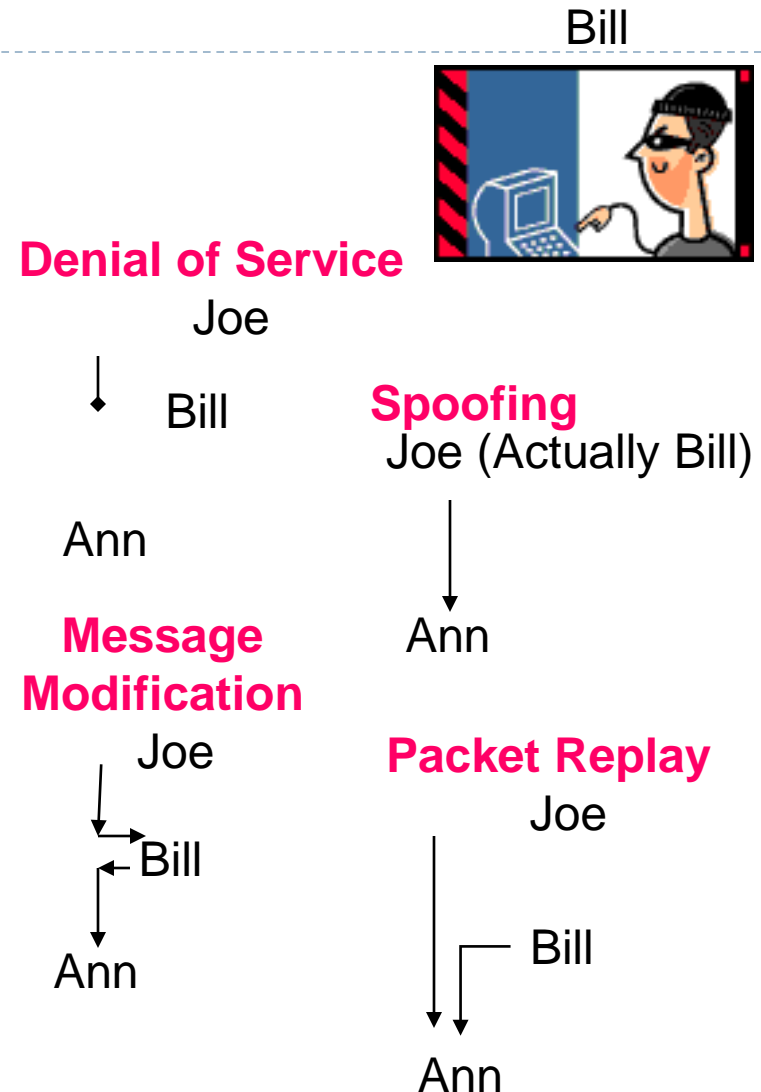

# Some Active Attacks

**Denial of Service:** Message did not make it; or service could not run

**Masquerading or Spoofing:** The actual sender is not the claimed sender

**Message Modification:** The message was modified in transmission

**Packet Replay:** A past packet is transmitted again in order to gain access or otherwise cause damage

# Common security attacks and their countermeasures

---

- ▶ **Finding a way into the network**
  - ▶ Firewalls
- ▶ **Exploiting software bugs, buffer overflows**
  - ▶ Intrusion Detection Systems
- ▶ **Denial of Service**
  - ▶ Ingress filtering, IDS
- ▶ **TCP hijacking**
  - ▶ IPSec
- ▶ **Packet sniffing**
  - ▶ Encryption (SSH, SSL, HTTPS)
- ▶ **Social problems**
  - ▶ Education

# Firewalls

---

Basic problem – many network applications and protocols have security problems that are fixed over time

- ▶ Difficult for users to keep up with changes and keep host secure
- ▶ Solution
  - ▶ Administrators limit access to end hosts by using a firewall
  - ▶ Firewall is kept up-to-date by administrators

# Firewalls

## *firewall*

isolates organization's internal net from larger Internet, allowing some packets to pass, blocking others

# Firewalls

---

**A firewall is like a castle with a drawbridge**

- ▶ Only one point of access into the network
- ▶ This can be good or bad

**Can be hardware or software**

- ▶ Ex. Some routers come with firewall functionality
- ▶ Windows XP and Mac OS X have built in firewalls

# Firewalls: why

---

## prevent denial of service attacks:

- ❖ SYN flooding: attacker establishes many bogus TCP connections, no resources left for “real” connections

## prevent illegal modification/access of internal data

- ❖ e.g., attacker replaces CIA’s homepage with something else

## allow only authorized access to inside network

- ❖ set of authenticated users/hosts

## three types of firewalls:

- ❖ stateless packet filters
- ❖ stateful packet filters
- ❖ application gateways

# Firewalls

---

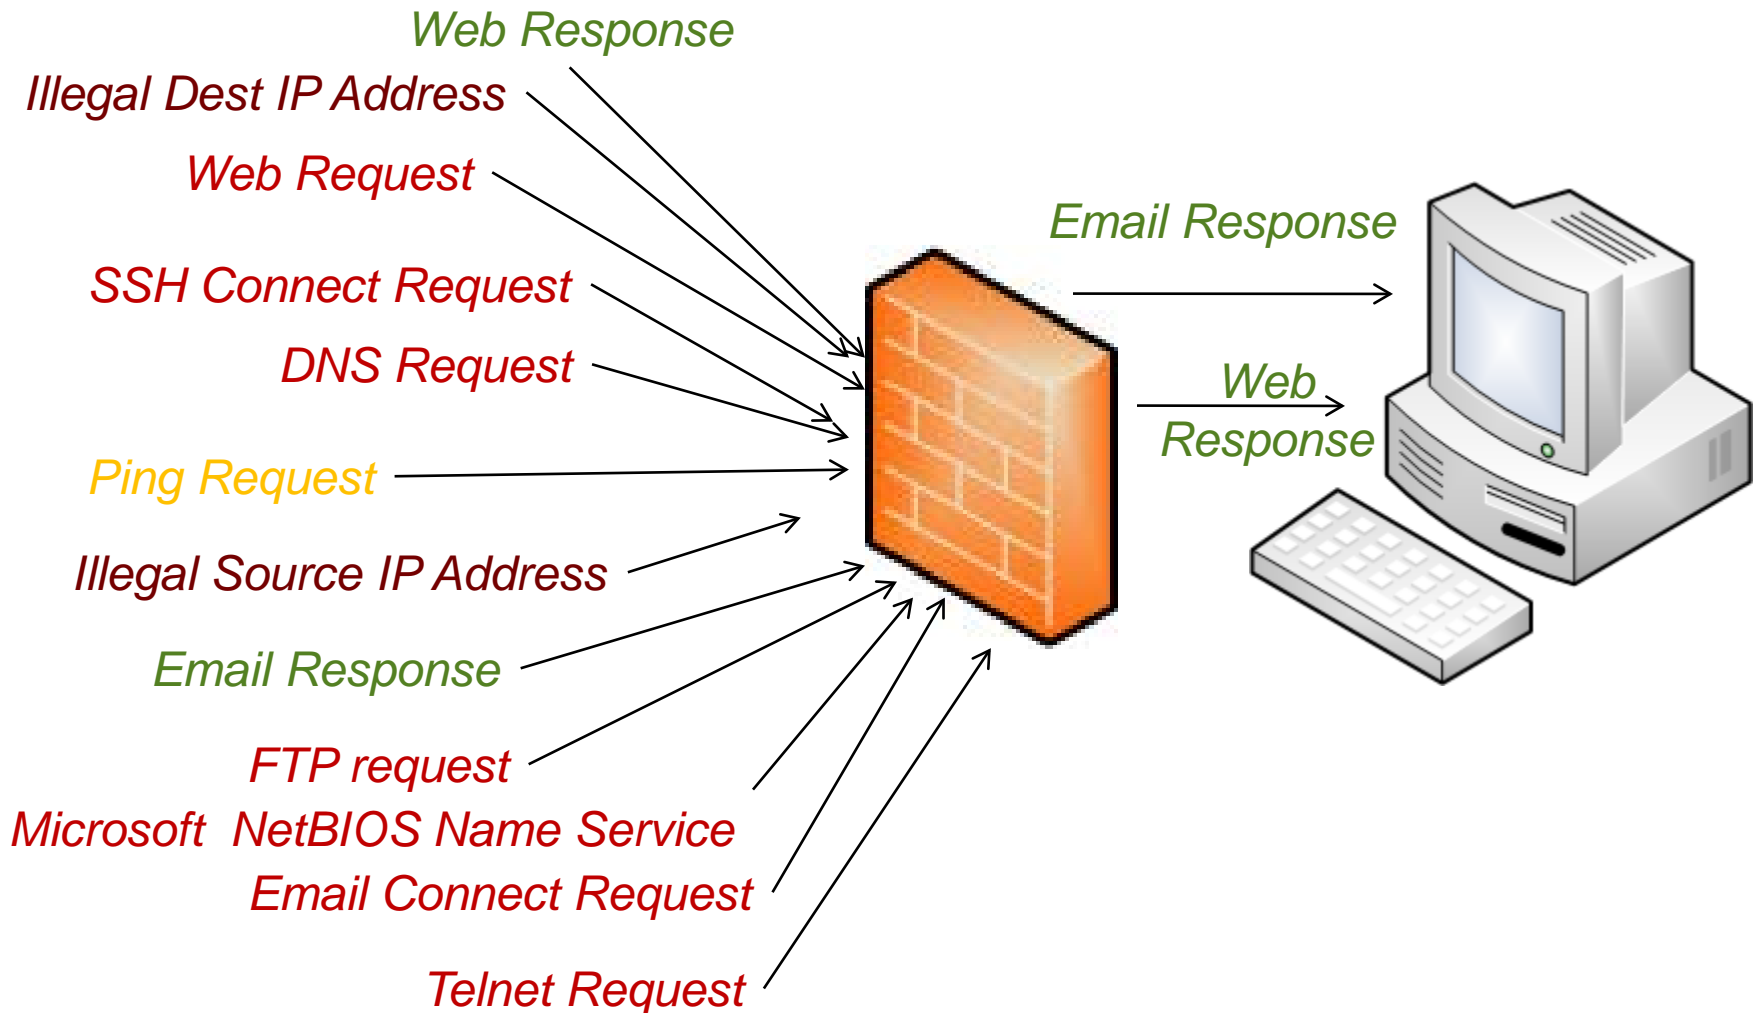

Used to filter packets based on a combination of features

- ▶ These are called packet filtering firewalls
  - ▶ There are other types too.
- ▶ Ex. Drop packets with destination port of 23 (Telnet)
- ▶ Can use any combination of IP/UDP/TCP header information

# Packet Filter Firewall

---

# Intrusion detection systems

---

- ▶ packet filtering:
  - ▶ operates on TCP/IP headers only
  - ▶ no correlation check among sessions
- ▶ *IDS: intrusion detection system*
  - ▶ *deep packet inspection*: look at packet contents (e.g., check character strings in packet against database of known virus, attack strings)
  - ▶ *examine correlation* among multiple packets
    - ▶ port scanning
    - ▶ network mapping
    - ▶ DoS attack

# Intrusion Detection

---

- ▶ Used to monitor for “suspicious activity” on a network
  - ▶ Can protect against known software exploits, like buffer overflows
- ▶ Open Source IDS: Snort, [www.snort.org](http://www.snort.org)
- ▶ Uses “intrusion signatures”
  - ▶ Well known patterns of behavior
    - ▶ Ping sweeps, port scanning, web server indexing, OS fingerprinting, DoS attempts, etc.

# Intrusion Detection Systems (IDS)

---

## Network IDS=NIDS

- ▶ Examines packets for attacks
- ▶ Can find worms, viruses, org-defined attacks
- ▶ Warns administrator of attack

## Host IDS=HIDS

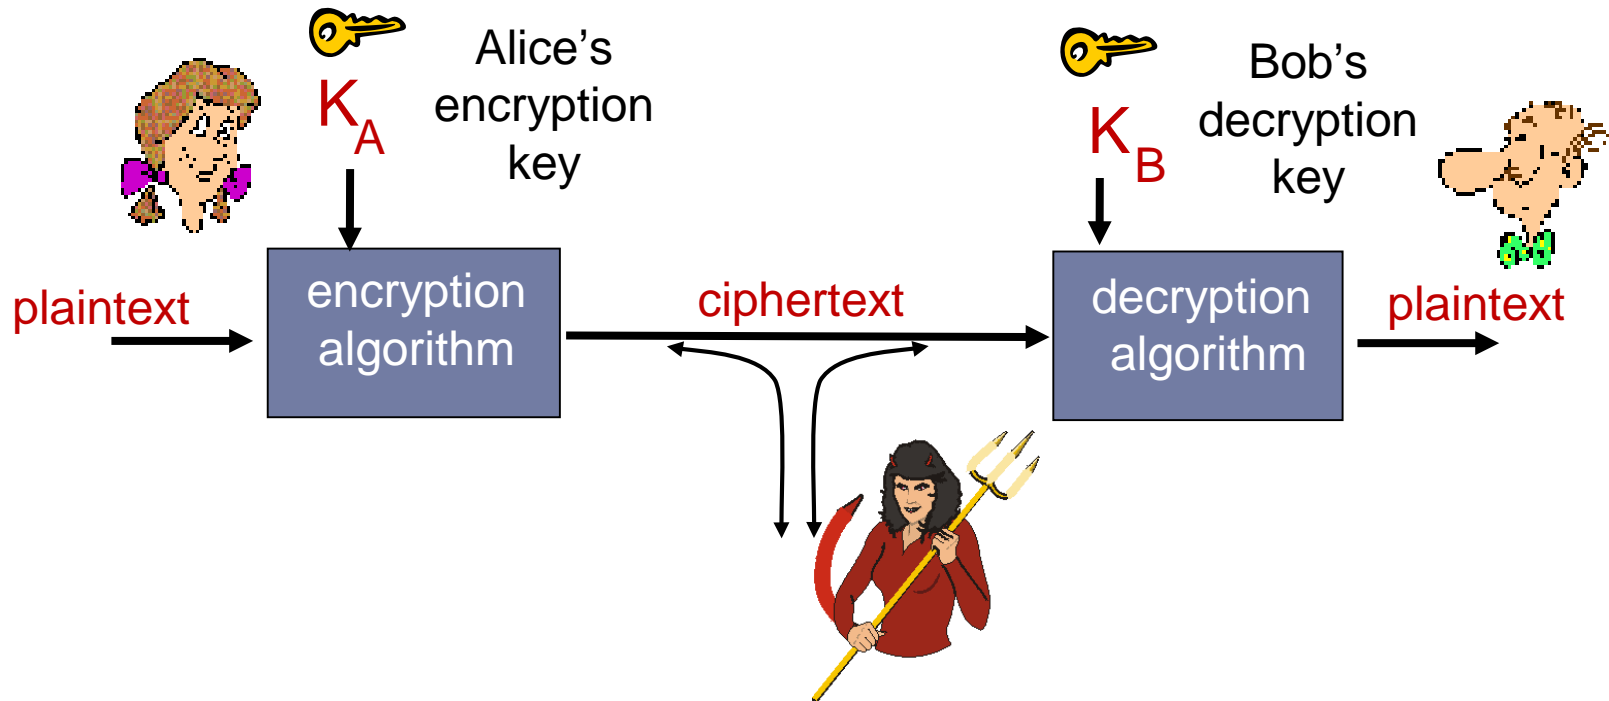

- ▶ Examines actions or resources for attacks
- ▶ Recognize unusual or inappropriate behavior
- ▶ E.g., Detect modification or deletion of special files

# Intrusion detection systems

- ▶ multiple IDSs: different types of checking at different locations

# The language of cryptography

$m$  plaintext message

$K_A(m)$  ciphertext, encrypted with key  $K_A$

$m = K_B(K_A(m))$

# Simple encryption scheme

*substitution cipher*: substituting one thing for another

- ▶ monoalphabetic cipher: substitute one letter for another

plaintext:	a	b	c	d	e	f	g	h	i	j	k	l	m	n	o	p	q	r	s	t	u	v	w	x	y	z
		↓																								↓
ciphertext:	m	n	b	v	c	x	z	a	s	d	f	g	h	j	k	l	p	o	i	u	y	t	r	e	w	q

e.g.: Plaintext: bob. i love you. alice  
ciphertext: nkn. s gktc wky. mgsbc

🔑 *Encryption key*: mapping from set of 26 letters  
to set of 26 letters

# Cryptography Techniques

---

- ▶ **Symmetric key cryptography:**
  - ▶ DES: Data Encryption Standard
  - ▶ AES: Advanced Encryption Standard
- ▶ **Public key cryptography:**
  - ▶ RSA : Rivest - Shamir -Adleman

# Dictionary Attack

---

- ▶ **We can run a dictionary attack on the passwords**
  - ▶ The passwords are encrypted with the crypt(3) function (one-way hash) at few places.
  - ▶ Can take a dictionary of words, crypt() them all, and compare with the hashed passwords
- ▶ **This is why your passwords should be meaningless random junk!**
  - ▶ For example, “sdfo839f” is a good password
    - ▶ That is not my password
    - ▶ Please don’t try it either
  - ▶ <https://howsecureismypassword.net/>

# Denial of Service

---

- ▶ **Purpose:** Make a network service unusable, usually by overloading the server or network
- ▶ **Many different kinds of DoS attacks**
  - ▶ SYN flooding
  - ▶ SMURF
  - ▶ Distributed attacks

# Denial of Service

---

- ▶ SYN flooding attack
- ▶ Send SYN packets with bogus source address
  - ▶ Why?
- ▶ Server responds with SYN ACK and keeps state about TCP half-open connection
  - ▶ Eventually, server memory is exhausted with this state
- ▶ Solution: use “SYN cookies”
  - ▶ In response to a SYN, create a special “cookie” for the connection, and forget everything else
  - ▶ Then, can recreate the forgotten information when the ACK comes in from a legitimate connection

# Denial of Service

---

## ▶ SMURF

- ▶ Source IP address of a broadcast ping is forged
- ▶ Large number of machines respond back to victim, overloading it

# Denial of Service

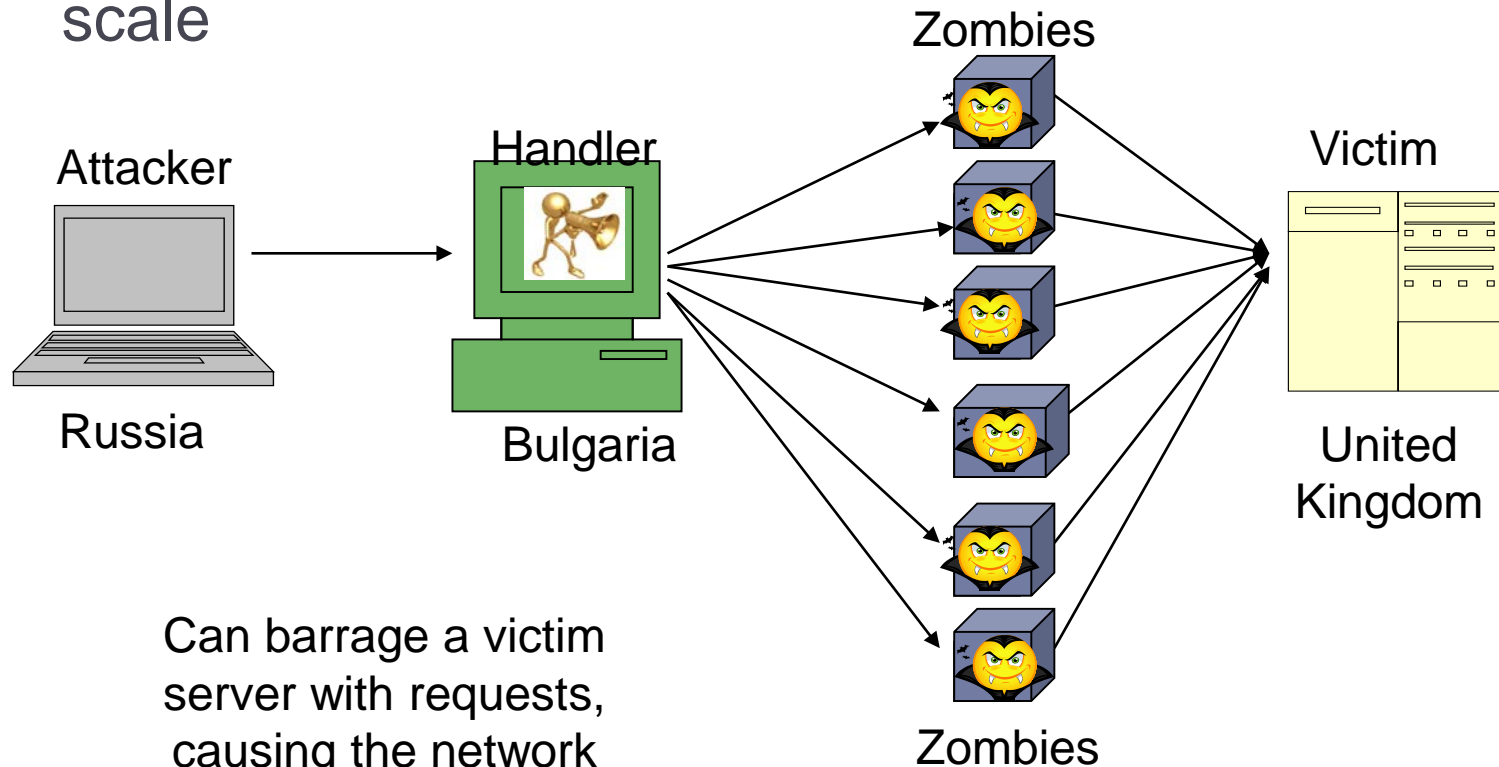

- ICMP echo (spoofed source address of victim)  
Sent to IP broadcast address
- ICMP echo reply

# Denial of Service

## ► Distributed Denial of Service

- Same techniques as regular DoS, but on a much larger scale

Can barrage a victim server with requests, causing the network to fail to respond to anyone

# TCP Attacks

---

- ▶ **Recall how IP works...**
  - ▶ End hosts create IP packets and routers process them purely based on destination address alone
- ▶ **Problem:** End hosts may lie about other fields which do not affect delivery
  - ▶ Source address – host may trick destination into believing that the packet is from a trusted source
    - ▶ Especially applications which use IP addresses as a simple authentication method
    - ▶ Solution – use better authentication methods

# TCP Attacks

---

- ▶ **TCP connections have associated state**
  - ▶ Starting sequence numbers, port numbers
- ▶ **Problem – what if an attacker learns these values?**
  - ▶ Port numbers are sometimes well known to begin with (ex. HTTP uses port 80)
  - ▶ Sequence numbers are sometimes chosen in very predictable ways

# TCP Attacks

---

- ▶ If an attacker learns the associated TCP state for the connection, then the connection can be **hijacked!**
- ▶ Attacker can insert malicious data into the TCP stream, and the recipient will believe it came from the original source
  - ▶ Ex. Instead of downloading and running new program, you download a virus and execute it

# TCP Attacks

---

- ▶ Say hello to Alice, Bob and Mr. Trudy

# TCP Attacks

---

- ▶ Alice and Bob have an established TCP connection

# TCP Attacks

---

- ▶ Mr. Trudy lies on the path between Alice and Bob on the network
  - ▶ He can intercept all of their packets

# TCP Attacks

---

- ▶ First, Mr. Trudy must drop all of Alice's packets since they must not be delivered to Bob (why?)

# TCP Attacks

---

- ▶ Then, Mr. Trudy sends his malicious packet with the next ISN (sniffed from the network)

# TCP Attacks

---

- ▶ How do we prevent this?
- ▶ **IPSec**
  - ▶ Provides source authentication, so Mr. Trudy cannot pretend to be Alice
  - ▶ Encrypts data before transport, so Trudy cannot talk to Bob without knowing what the session key is

# IPsec services

---

- ▶ data integrity
- ▶ origin authentication
- ▶ replay attack prevention
- ▶ confidentiality
  
- ▶ two protocols providing different service models:
  - ▶ AH
  - ▶ ESP

# Two IPsec protocols

---

- ▶ **Authentication Header (AH) protocol**
  - ▶ provides source authentication & data integrity but *not* confidentiality
- ▶ **Encapsulation Security Protocol (ESP)**
  - ▶ provides source authentication, data integrity, *and confidentiality*
  - ▶ more widely used than AH

# Packet Sniffing

---

- ▶ Recall how Ethernet works ...
- ▶ When someone wants to send a packet to some else ...
- ▶ They put the bits on the wire with the destination MAC address ...
- ▶ And remember that other hosts are listening on the wire to detect for collisions ...
- ▶ It couldn't get any easier to figure out what data is being transmitted over the network!

# Packet Sniffing

---

- ▶ This works for wireless too!
- ▶ In fact, it works for any broadcast-based medium

# Packet Sniffing

---

- ▶ What kinds of data can we get?
- ▶ Asked another way, what kind of information would be most useful to a malicious user?
- ▶ Answer: Anything in plain text
  - ▶ Passwords are the most popular

# Social Problems

---

- ▶ People can be just as dangerous as unprotected computer systems
  - ▶ People can be lied to, manipulated, bribed, threatened, harmed, tortured, etc. to give up valuable information
  - ▶ Most humans will breakdown once they are at the “harmed” stage, unless they have been specially trained
    - ▶ Think government here...

# Social Problems

---

## ▶ Example:

- ▶ Someone calls you in the middle of the night
  - ▶ “Have you been calling Egypt for the last six hours?”
  - ▶ “No”
  - ▶ “Well, we have a call that’s actually active right now, it’s on your calling card and it’s to Egypt and as a matter of fact, you’ve got about £2000 worth of charges on your card and ... read off your card number and PIN and then I’ll get rid of the charge for you”

# Conclusions

---

- ▶ The Internet works only because we implicitly trust one another
- ▶ It is very easy to exploit this trust
- ▶ The same holds true for software
- ▶ It is important to stay on top of the latest security advisories to know how to patch any security holes
